Paper Forthcoming in 2014 Transportation Research Record

March 13, 2014

7,452 words [6,452 + 4 Figures x 250]

**ABSTRACT**

This research aims in part to understand if different bicycling technology, in this case electric assist bicycles or e-bikes, can reduce barriers to bicycling, including trip distance, topography, time, and rider effort. Doing so may result in more bike trips and longer bike trips, and increase the diversity of people bicycling, including people with a disability or chronic injury. E-bikes typically resemble a standard pedal bicycle with the addition of a rechargeable battery and electric motor to assist the rider with propulsion. To address these aims, we conducted an online survey of existing e-bike users on their purchase and use decisions. Responses from 553 e-bike users across North America are analyzed here. Results suggest that e-bikes are enabling users to bike more often, to more distant locations, and to carry more cargo with them. Additionally, e-bikes allow people who would otherwise not be able to bike because of physical limitations or proximity to locations, the ability to bike with electric assist.

## INTRODUCTION

As the U.S. continues to urbanize and transportation funding becomes scarce, municipalities are increasingly looking to reduce reliance on single occupant motor vehicles in favor of bicycling, walking, and public transportation. These active transportation modes are attractive due to their reduced greenhouse gas (GHG) emissions, reduced road and parking space, and associated health benefits. To date, most efforts have been to increase these modes through changes in infrastructure, land use, and awareness programs. While these are critical elements in mode choice decisions, less research exists on improving the technology and usability of the mode itself to encourage more trips to be made by bike and for more people to take bike trips. This research focuses on electric assist bicycles or “e-bikes” and whether this technology can encourage more bike trips and longer bike trips, and increase the number of people biking by attracting people who typically do not or cannot ride a regular bicycle. By increasing the amount of biking, positive benefits could be realized in terms of reduced vehicle emissions and an increase in physical activity and mental well-being.

This paper includes a literature review focused on common barriers to bicycling and existing e-bike research. The literature review is followed by findings from an online survey of existing e-bike users. The purpose of the survey is to better understand the factors that influence purchase decisions and how current users in North America use their e-bikes. Survey responses were analyzed to determine if some of the barriers to biking can be addressed by e-bikes.

## BACKGROUND

U.S. cities are faced with many transportation challenges such as traffic congestion, injury and loss of life from road crashes, local air quality, climate change, obesity and physical inactivity, economic burdens, and international supplies of oil. Shifting people out of cars to other modes of transportation, such as bicycling, can help address these challenges. With an increased focus on reducing the effects of motor vehicles in metro regions, planners and policy makers are looking to increase the attractiveness of walking and bicycling.

There are many factors (i.e., adequate infrastructure and supportive policies) that affect the extent to which bicycling will be a viable transportation mode in urban and suburban communities (1). According to the 2009 Nationwide Household Travel Survey (NHTS), 57% percent of daily vehicle trips are under five miles in length – a reasonable distance to ride a bike (2). Even with extensive bike infrastructure, riders must be willing and physically able to operate bikes for a full range of trips. Because of this, bicycle trips tend to be shorter than motor vehicle trips and cyclists tend to avoid hilly locations (3). If urban and suburban areas want to increase the numbers participating in biking, barriers for some individuals must be addressed.

One possible solution to increase biking in urban areas is through wider adoption of e-bikes. By providing electric power assistance to a rider, the potential role of the bicycle, especially for commuting and errands, can be expanded by addressing the limits of trip distance and terrain. In addition to distance and terrain, e-bikes have the potential to overcome other barriers to biking that have been identified in previous studies (4, 5).

### Barriers to Biking

In the U.S., research has found that men bike at a significantly higher rate than women. Pucher, Buehler, and Seinen found the 2009 NHTS showed that women made 24% of all bike trips with men making up the remaining 76% (6). This is consistent with a study that found men's total bike trips surpass women's by a ratio of at least 2:1 (7). In contrast, industrialized European countries such as the Netherlands, Denmark, and Germany tend to have equal or higher rates of female cyclists compared to male cyclists (8). Past research has shown that factors that keep women from biking more include: increased concern for safety, the need to make multiple stops while hauling items such as groceries, and transporting passengers (9). Baby boomers came of age during the automobile era and yet as a whole, this group is

more physically active than any previous generation. A report by the AARP Public Policy Institute states that there is renewed interest from older adults in alternatives to the automobile, such as bicycles (10). Past research has shown that older bike riders can have difficulty navigating intersections, left hand turns, and maneuvering the bicycle (11). As the baby boom generation ages, their continued mobility and accessibility needs will increase as their numbers increase.

In a survey of the bike commute literature, Heinen and colleagues found that barriers to biking include: safety, weather, inconvenience, lack of fitness, lack of time, being tired, too much effort, and difficulties with trip chaining (9). These barriers can be more or less significant based on an individual's age, fitness, or physical ability. Infrastructure improvements, destinations and destination amenities can address some of these concerns related to safety and distance but fail to address other barriers related to the individual rider such as fitness, topography, and effort. Distance and topography can be tied to many of the barriers to biking that include lack of fitness, lack of time, being too tired, too much effort and difficulties with trip chaining. E-bikes could allow people with physical limitations, older adults, and people in geographically challenging areas to participate in bicycling (5, 12).

### **Electric Bikes**

E-bikes typically resemble a standard pedal bicycle with the addition of a rechargeable battery and electric motor to assist the rider with propulsion. E-bike makes and models vary widely in their technology. This paper will focus on e-bikes that are essentially standard bicycles that have a battery and small motor to assist the rider with propulsion. Electric scooters with or without pedals are not considered e-bikes for the purposes of this paper. The location of the batteries and motors on the e-bike vary from model to model. Many e-bikes place a motor either on the front or rear wheel hub of the bicycle. Alternatively, e-bike motors can be located near the middle of the bicycle around the crank area to provide assistance to the crank or chain. Batteries can be built into the frame of the e-bike, mounted externally or within a rear rack. Some researchers make a distinction between powered bicycles (PBs) and power-assisted bicycles (PABs), also referred to as "pedelecs". The critical difference between PBs and PABs is that on the former, the motor operates with a switch or throttle without any pedaling from the rider, on the latter, power assistance is only provided when the rider is pedaling (13). The e-bike as we know it today originated in Japan sometime during the early 1980s with the intent of making bicycling easier for the elderly (14).

Federally, the Consumer Product Safety Act defines a low-speed electric bicycle as a "two-or three-wheeled vehicle with fully operable pedals and an electric motor of less than 750 watts (1 horse power), whose maximum speed on a paved level surface, when powered solely by such a motor while ridden by an operator who weighs 170 pounds, is less than 20 mph" (15). Individual states may have their own definitions and requirements with respect to use and operation of e-bikes that are more stringent than the federal law. Many states do not have specific e-bike regulations at this time but that may change if this technology continues to expand. As of this paper, we found that 18 of 50 U.S. states had e-bike specific regulations. Some municipalities in the U.S. specifically prohibit e-bikes on multi-use paths or city streets (16, 17, 18).

The worldwide market for e-bikes is growing but varies geographically. According to Navigant Research, worldwide sales of e-bikes were expected to be 30 million units in 2012 and 47.6 million by 2018 with the majority of sales being in Asia. In China alone, 120 million e-bikes (includes scooter and mopeds) were operating in the country as of 2010 and a total of 200 million were expected to be on roads by 2012. In the U.S., e-bike sales in 2012 were approximately 53,000. Comparatively, approximately 252,000 e-bikes were sold in Germany, a country with less than one-third the population of the U.S. (19). Because of limited numbers in North America, e-bikes can still be considered in the "early adopter" phase though U.S. consumers are being presented with a broader range of e-bike options through specialty bicycle stores, online stores and electronic retail outlets. Mainstream use of e-bikes in the U.S. has been hampered by low retail availability, cost of units, lack of knowledge about the technology and issues effecting general bike use; such as, inadequate infrastructure investments and a lack of comprehensive, integrated policies and programs to promote bicycling and cycling safety (6).

The majority of the e-bike research has focused on use and adoption in China and Europe. In 2006, Weinhart et al. detailed results of intercept surveys on consumer travel behavior and attitudes of 460 e-bike user in Shijiazhuang, China (20). More recently, Johnson and Rose looked to understand the Australian e-bike market (21). These studies show that e-bikes are used by a variety of individuals to bike further distances and to overcome barriers to biking, such as trip length, cargo weight or physical limitations. One of the striking differences in the studies and with this study is that Shijiazhuang e-bike users were evenly split between male and female and 73% were between 24 and 40 years old (20). The Australian and North American users tend to be older and male.

## METHODS

Existing e-bike owners and users, primarily in the U.S., were surveyed using an instrument adapted from the Institute of Transport Studies at Monash University in Melbourne, Australia (21). The e-bike survey was administered online starting March 7, 2013 and remained open until July 1, 2013. The survey link was distributed through e-bike blogs, online forums, Facebook pages, Twitter accounts, e-mails to manufacturers and retailers, and via postcards left in local bicycle shops in the Portland region. Closed-ended responses were analyzed using SPSS to identify trends and differences. The survey included a number of questions with the opportunity for the participant to include open-ended text responses. These responses were analyzed and grouped into major themes where possible.

Five hundred and fifty-three people who own or use an e-bike regularly in the U.S. or Canada took the survey, though not everyone answered all questions. Because the individuals were not a random sample and there is very limited knowledge of actual e-bike ownership in the North America, findings may not accurately represent the population of e-bike owners. FIGURE 1 shows the geographic distribution of survey respondents across the U.S. and Canada. Concentrations of respondents are observed in Southern California, the San Francisco Bay Area, the Pacific Northwest and along the northeastern corridor.

## FINDINGS

### Demographics/Purchase Decision

TABLE 1 presents the user characteristics of the e-bike survey respondents. Respondents were predominately male (85%) and 71 percent of them were 45 years of age or older. Ninety percent of survey respondents identified themselves as white with 71 percent reporting that they were a college graduate or had obtained a graduate degree. Respondents reported on their general state of health with 58 percent indicating that they were in very good or excellent condition. Nearly one-third (30%) of respondents stated that they had a physical condition that makes riding a standard bike difficult. Respondents listed knee problems, arthritis, asthma, and back pain as common ailments.

Respondents were nearly evenly split between e-bike conversions of a standard bike (52%) and purchases of new, fully assembled e-bikes (48%). Cargo bikes and increasing cargo capacity were cited by respondents for reasons to convert their standard bicycle to an e-bike. Respondents indicated that increasing the hauling capacity of their bicycle was one of the main reasons they bought or converted a standard bicycle at 14 percent of open ended responses. When asked the reasons for changing from a standard bike to an e-bike in an open ended question, 8 percent of respondents listed increased cargo capacity. Respondents that converted standard bikes to e-bikes did so using a mountain bike almost 40 percent of the time. The next most common conversion was hybrid bikes at 16 percent, cargo bikes/trikes at 13 percent and recumbent bikes at 11 percent followed by road bikes, women's bikes/commuters, other and folding bikes. Two-thirds of respondents (66%) had purchased their e-bike or conversion kit in the past two and a half years. This information is consistent with reports that e-bike sales have increased over the past few years (14). When asked how the electric power turns on for their e-bike, 46 percent of respondents said that their e-bike either had a grip or thumb throttle on the handlebar. Thirty percent of respondents indicated that their e-bike had an on/off button and 13 percent said that their e-bike only provides assistance when pedaling. The remaining 11 percent of respondents chose "other" with 65

percent indicating that their e-bike had a pedal assist option in addition to a throttle and the remaining 35 percent described an ignition or switch to activate the power assistance.

When asked how much their e-bike or conversion kit cost to purchase, the responses varied within categories from \$500 or less to \$2,501 or more. Twenty-two percent of respondents indicated that their e-bike or conversion kit cost was \$1,000-\$1,500. The least populated price category was the \$2,001-2,500 range with only 10 percent of respondents. When price was compared to conversion type, differences in purchase price were more apparent with those who converted a standard bike in general spent less than respondents who purchased an e-bike.

Many, but not nearly all, of the e-bike users were standard bike riders prior to getting their e-bike. Ninety-four percent of respondents indicated that they rode a standard bike as an adult before owning an e-bike, but only 55 percent rode a standard bike either weekly or daily prior to e-bike purchase. When asked how often they ride a standard bike now, 31 percent indicated weekly or daily. Interestingly, 6 percent of respondents didn't ride a standard bike as an adult before they purchased an e-bike and 89 percent of them now ride daily or weekly.

The majority of e-bike survey respondents (90%) indicated that they have access to a motor vehicle at home and 91 percent have a license for a motor vehicle. Seven percent of respondents reported having zero motor vehicles in their household and 72 percent reported that they had one or two motor vehicles. Nearly one-third (33%) of respondents reported that 61 percent or more of their trips were by e-bike. Household size was predominately one or two persons (65%), reflecting the majority of older adult respondents.

### **Motivations for Purchasing an E-bike**

Respondents were asked about the main reasons they bought or converted an e-bike, with the ability to indicate multiple reasons. Nearly 65 percent of respondents stated that one of the main reasons they bought or converted an e-bike was to replace some car trips. Twenty-one percent of respondents indicated that one of the main reasons for converting to an e-bike was a medical condition reduced their ability to ride a standard bike and 52 percent of respondents indicated that one of the main reasons was to increase fitness. Nearly 60 percent of respondents indicated that one of the main reasons was because they live or work in a hilly area and 55 percent said that they wanted to ride with less effort. The reason with the least percentage of respondents was to keep up with friends/family, 11 percent of respondents chose this as one of the main reasons they bought or converted an e-bike.

When these responses are disaggregated by gender, age and physical ability some differences emerge. Results are shown in TABLE 2. Fifty-six percent of females chose "because you live or work in a hilly area" compared to 40 percent of males. Females also chose to be able to keep up with friends/family as one of the main reasons 23% compared to males at nine percent. Sixty-five percent of respondents that identified as having a physical limitation that prevents them from riding a standard bike indicated that one of the main reasons they bought an e-bike was "to ride with less effort" compared to 53% of those without a physical limitation. Notable differences exist between older (55+) and younger (under 55) adults. Sixty-one percent of older respondents indicated that one of the main reasons was to replace some car trips compared to 72% of those under 55. Similar differences can be observed in the other main reasons listed in TABLE 2.

One-hundred and seventeen respondents chose "other" as a main reason for buying or converting an e-bike. Twenty-eight percent of these responses listed fun as the reason, 23 percent indicated that they wanted to travel farther or faster by bike, 14 percent listed increased hauling capacity with hobby, saving money, driving not being an option and to keep up with traffic/safety comprising the other answers.

### **Electric Bike Use**

The survey responses indicate that e-bikes may be increasing overall levels of bicycling. When asked how often they rode a standard bike before owning an e-bike, 55 percent of respondents indicated that they rode weekly or daily. When asked how often they ride their e-bike, 93 percent of respondents replied that they ride weekly or daily. Some of this difference may be attributed to response bias (the most

enthusiastic owners are more likely to take the survey), though that may not account for the large difference (55% versus 93%).

E-bikes appear to be used primarily for utilitarian travel. Respondents were asked to pick the main reason that they used their electric bike. In aggregate, 45 percent of respondents chose commute to work/school as the main reason that they used their e-bike with local trips accounting for 24 percent, recreation at 20 percent and 11 percent chose other. The majority of respondents that chose other wanted an option for all of the above. When these responses were disaggregated by gender, physical ability and age, some differences emerged. Males were more likely to use their e-bikes for recreation compared to females with 20 percent of males choosing recreation as the main reason they use their e-bike versus 13 percent of females. Respondents with a physical limitation were less likely to use their e-bike to commute to work than those without a physical ability, 31 percent versus 51 percent respectively. Consequently, 28 percent of those with a physical limitation responded that they use their e-bike for recreation compared to 16 percent of respondents without a physical limitation. Thirty-one percent of respondents 55 and older use their e-bikes for recreation compared to nine percent of those under 55. Commute trips were much higher for respondents under 55 (58%) compared to those 55 and older (30%). This difference may be explained by the probability that fewer respondents 55 and older are in the workforce.

E-bikes do appear to be changing the way bicyclists ride. Forty-five percent of respondents indicated that they take a different route on their e-bike than they did on their standard bike. When segregated by gender, 51 percent of females responded that they take a different route compared to 44 percent of males. In an open-ended question, respondents that indicated that they take a different route listed the routes they take on their e-bike. Thirty-five percent of respondents indicated that they do not avoid hills on their e-bike as compared to a standard bike. Thirty-one percent of respondents indicated that they take a more direct or higher traffic route on their e-bike and interestingly, 30 percent indicated that they take a lower traffic or less direct route. The remaining responses listed avoiding off street or multi-use paths to limit confrontation with other users.

Some of the advantages of an e-bike include being able to travel further, accelerate more easily, travel faster, and ride up hills more easily. These advantages were evident among our respondents. Seventy-three percent of respondents indicated that they ride their e-bike to different destinations than they did on their standard bike. Again, there was a difference by gender with 79 percent of females indicating that they ride to different destinations compared to 71 percent of males. Respondents that ride to different destinations were asked what those destinations are in an open ended format. Nearly 34 percent indicated that they ride to places that are farther away. Another third listed errands or social events as a different destination that they ride to on their e-bike. Sixteen percent listed commute as a different destination, 10 percent indicated recreational trips and seven percent listed hillier destinations or origins.

When asked how often they stop and wait at all stop signs on their e-bike, 54 percent chose always. When asked the same question for riding their standard bike, 25 percent chose always but 10 percent chose not applicable presumably because they do not currently ride a standard bike. When asked a series of questions on if their top speed and average speed was higher than when they rode a standard bike, the vast majority of respondents either agreed or strongly agreed. In the same set of questions participants were asked to agree or disagree with statements about not needing a shower at the end of their trip and if they were to make the same trip by a standard bike they would need a shower. Here again, respondents agreed or strongly agreed that they don't need a shower at the end of the trip (74%) and that they would need a shower if they had ridden a standard bike (67%).

When this data are disaggregated by gender, age and physical limitations some differences are more apparent as seen in TABLE 3. Seventy-one percent of respondents 55 and older agreed or strongly agreed that their top speed is higher on an e-bike than a standard bike compared to 65 percent of respondents under the age of 55. When asked to agree or disagree about their average speed being higher on an e-bike, 86 percent of males either agreed or strongly agreed compared to 77 percent of females. When asked to agree or disagree with the statement "I don't need to shower at the end of the trip", 80 percent of respondents under the age of 55 either agreed or strongly agreed compared to 68 percent of

those 55 and older. This could be partly explained by how older adults use their e-bikes, a higher percentage of older adults use their e-bikes for recreation. When asked if they would need a shower to ride the same trip on a standard bike, 69 percent of males either agreed or strongly agreed compared to 55 percent of females.

### Safety and Maintenance

Other research questions focused on the effect of e-bikes may have on safety and safety perceptions. When asked to agree or disagree with the statement, "I feel safer on the e-bike than on a standard bike", 60 percent of all respondents either agreed or strongly agreed. When asked if they ever had any crashes on the e-bike, 34 percent of respondents indicated that they had. Of the 34 percent that responded that they had experienced a crash, 10 percent stated that the e-bike contributed to the crash. Participants were asked to describe their crash in an open ended question, responses varied widely from problems with increased speed and weight, to rider error and conflicts with other road users. Alternatively, when asked if the e-bike helps them avoid crashes, 42 percent replied yes. When asked to describe how the e-bike helps them avoid crashes in an open ended question, responses included acceleration to get out of intersections more quickly, keeping up with car traffic, and better balance at higher speeds.

When asked to rank where they typically recharge their e-bike, 83 percent ranked home as the primary location. The workplace was ranked as the second most frequent recharge location at 52 percent. Destinations ranked as the third most frequent charging location with 37 percent of responses. Fifty-three percent of respondents indicated that the battery has run out when they were out riding. An open ended follow-up question asked what they did when the battery ran out. Ninety percent of respondents indicated that they pedaled when the battery ran out. Other answers included switching batteries, recharging somewhere, walking the bike home, calling for a ride or using transit. The respondents were asked where they get their bike serviced, 58 percent responded that they service it themselves and 31 percent had it serviced where they had purchased the bike. Another electric bike retailer (8%) and private service (3%) were less popular locations for service. When asked how often their e-bike needs to be serviced compared to a standard bike, 49 percent indicated that it was about the same and 27 replied more often than a standard bike.

### User Perceptions

When respondents were asked if they ever had any reactions – positive or negative – from other road users, 36 percent of respondents indicated that they had positive reactions, followed closely by curiosity at 34 percent. Alternatively, 20 percent of respondents indicated that they had negative or angry reactions and 10 percent used the word cheating explicitly. The perceptions of existing users may be useful in developing marketing messages for non-users, some of whom who may have negative opinions of e-bikes. Participants provided the main advantages and disadvantages to riding an e-bike in an open ended question. Responses varied widely with no clear advantage dominating. Equal shares (18%) cited increased speed and range and to ride with less effort or help with hills. The third most frequent response included health advantages of riding an e-bike (16%). Cheaper transportation, fun and replacing car trips/ environmental reasons were cited by about equal shares of respondents (11-12%).

Weight was cited as the main disadvantage by 26 percent of respondents and perhaps surprisingly, cost and limited range each were mentioned by only eight percent of respondents. This could be due to the fact that participants taking the survey had already made the initial e-bike purchase. Fourteen percent of respondents cited inclement weather as the main disadvantage to riding an e-bike. It is unclear how many of these responses were specific to inclement weather negatively affecting the e-bike compared to those who did not want to be exposed to the elements themselves. Thirteen percent of respondents took the time to type that there are no disadvantages to riding an e-bike.

## DISCUSSION OF RESULTS AND CONCLUSIONS

The objectives of this paper were to understand the factors that influence purchase decisions and use of e-bikes by existing users and to analyze participant responses and compare them to barriers to bicycling to determine if e-bikes can address these barriers and encourage more biking. The analysis presented here suggests that e-bikes are enabling users to bike more often and to increase the amount existing cyclists bike. Additionally, e-bikes allow people who would otherwise not be able to bike because of physical limitations or proximity to locations, the ability to overcome these challenges to bike with electric assist.

Results show e-bikes have the potential to get more people to bike. From previous research, some primary barriers to encourage new people to participate in biking include inconvenience, safety, and amount of effort to bike, including distance traveled and physical limitation (9). Results show demographics of e-bike users to include populations that tend to bike less – women, older adults, people with physical limitations, and people with longer distances to travel. Though only 15% of the respondents were women, this still represents a sizeable number since this is a new technology and many of earlier year e-bikes were owned by men and are conversions. The following comments from respondents illustrate these points:

*I live in a hilly town and would never commute to work on a standard bike -- I wouldn't be able to make it up the hills. My electric assist bike makes commuting by bike possible.*

*I am age 78, legally blind, live alone in a semi-rural area. 4 miles to the nearest scheduled bus route and town, 7 miles to my favorite shopping area, 12 miles to my church.*

*I cannot drive due to epilepsy. I cannot bus due to severe motion sickness. Biking is my only way to work other than getting a ride. Bike commuting maintains my fitness level. I can ride even when I don't feel physically well or am overtired. I get to work faster than it takes when I get a car ride. I love the time outdoors, seeing the city and feeling like part of the bike community.*

On the goal of encouraging more people to bike more often and to bike to more distant locations, results show a positive relationship of having an e-bike and the increase in riding. Six percent of the respondents stated that they did not ride a bike as an adult until purchasing an e-bike and 89 percent of them now ride daily or weekly. Of the people owning a standard bike as an adult, 55 percent indicated that they rode their standard bike daily or weekly before purchasing an e-bike. That number rose to 93 percent after purchasing an e-bike. Respondents also indicated that they are biking farther distances less sweaty or tired than with a standard bicycle, they are not avoiding certain trips, destinations and hills and they enjoy the experience of bike riding.

One of the primary advantages stated was the ability of biking with less effort. This benefit plays out in different populations. For older adults and people with physical limitations, it means having an easier time biking and it is not as strenuous. For younger people, it means the ability to travel farther distances and not exerting too much effort to cause perspiration while riding. The following comments from respondents highlight these points:

*I get more exercise with the e-bike because I ride more.*

*E-bikes are a fantastic replacement for a car for short distances.*

*I can ride to and from work without needing to shower at my destination.*

*I use the e-bike primarily as a substitute for the car where I would have otherwise would have driven a car.*

*I can carry my son and a week's worth of groceries.*

Assessing the net effects of these shifts – more biking but with less effort – on physical activity was not an objective of this research. However, the findings indicate that the net effect may be positive. About two-thirds of the users got their e-bike to replace car trips, and 30% have physical limitations that make riding a standard bike difficult. Our survey respondents also indicated that they are riding more often than they rode their standard bike (if they did at all). In addition, research indicates that even with the electric assist, e-bikes can enhance health. At least three separate studies testing adults in laboratory-type setting found that the even with the electric assist, an e-bike provided moderate to vigorous physical activity (22, 23, 24). These researchers concluded that the e-bikes could lead to health benefits because the reduced perception of effort could get people to bicycle more.

Overall this research offers insights about existing e-bike owners to help identify potential policy issues and areas for future research. To date, little research has been completed on how improvements in bicycling technology can encourage more trips to be made by bike and for more people to take bike trips. Any time a new technology is adopted, there are issues and challenges that arise in its use. Some of those issues explored in the survey where related to cost, battery life, safety and conflicts, and perceptions of other cyclists and motorists. All these topics should be explored in more detail, especially issues around safety and perceptions from others. In areas of the country, where e-bike usage is increasing there could be policy issues that influence the adoption of e-bikes, as seen in New York and Toronto. For example, there is concern on how e-bikes interact with standard bikes and pedestrians on shared facilities. Issues of speed, safety, and operator behavior should be explored. About 20 percent of the respondents noted negative feedback from other cyclists and motorists. Some negative feedback (10%) was related to perceptions that e-bike riders were seen as cheating. This perception may be a function of awareness and social acceptance as more people adopt the technology.

This study was the first known nationwide survey of e-bike users in North America but it still only reached an unknown fraction of the total North American e-bike owners. We acknowledge that these results are not based upon a random sample of e-bike owners and may not be necessarily representative of the population, but they are perhaps indicative of general decision factors and uses by individuals. Because of the low adoption rates in the U.S., a random sample survey is not economically feasible at this time. We received lower than expected representation from female riders. Because this is a crucial group to encourage to cycle more often, further research should look into women and e-bikes. Additionally, further research is needed to consider the implications of e-bikes on physical activity. Future studies could examine how, when, and to what extent users engage in power assistance in conjunction with pedaling. Finally, more insight is needed to understand how e-bikes might replace trips by standard bike, transit, or car.

## ACKNOWLEDGMENTS

This research was supported by the Oregon Transportation Research and Education Consortium (OTREC) and Portland State University. The authors gratefully acknowledge Geoffrey Rose and Marilyn Johnson at the Institute of Transport Studies, Monash University for allowing us to use their survey instrument. In addition, we thank the faculty and staff at Portland State University for their assistance and support and the people who participated in the survey.

**FIGURE 1 - Locations of Survey Respondents**

**TABLE 1 - Respondent Characteristics (n = sample size)**

<i>Gender</i>	n=553
Male	85%
Female	15%
<i>Age</i>	n=451
18 to 24	1%
25 to 34	10%
35 to 44	18%
45 to 54	26%
55 to 64	32%
65 and over	13%
<i>Ethnicity</i>	n=428
White	90%
Black or African American	0%
Asian or Asian-American	5%
American-Indian or Alaskan Native	0%
Native Hawaiian or other Pacific Islander	0%
Other	5%
<i>Education</i>	n=448
High School	4%
Some College	25%
College Graduate	37%
Graduate Degree	34%
<i>Health</i>	n=449
Excellent	21%
Very Good	37%
Good	31%
Fair	9%
Poor	2%
<i>Do you have any physical limitations that make riding a standard bike difficult?</i> n=450	
Yes	30%
No	70%

**TABLE 2 – Motivations for Purchasing and Using an E-bike**

	Male Percent	Female Percent	Respondents with physical limitation Percent	Respondents without a physical limitation Percent	Respondents Under 55 Percent	Respondents 55 and Older Percent
<b>What were the main reasons you bought an electric bike, or converted a standard bicycle?</b>						
To replace some car trips	69%	61%	<b>56%</b>	<b>72%</b>	<b>72%</b>	<b>61%</b>
Health - medical condition reduced your ability to ride a standard bike	23%	20%	<b>59%</b>	<b>6%</b>	<b>13%</b>	<b>33%</b>
Health - to increase physical fitness	54%	57%	60%	52%	<b>49%</b>	<b>61%</b>
Because you live or work in a hilly area	<b>40%</b>	<b>56%</b>	41%	43%	41%	44%
To ride with less effort	57%	51%	<b>65%</b>	<b>53%</b>	<b>51%</b>	<b>63%</b>
To be able to keep up with friends/family when I go for rides	<b>9%</b>	<b>23%</b>	<b>20%</b>	<b>8%</b>	<b>9%</b>	<b>15%</b>
Sample size (n)	381	70	133	317	249	202
<b>What is the main reason that you use your electric bike (purpose of trips)?</b>						
Commute to work/school	45%	49%	<b>31%</b>	<b>51%</b>	<b>58%</b>	<b>30%</b>
Local trips (shopping and errands)	24%	27%	27%	23%	21%	29%
Recreation	20%	13%	<b>28%</b>	<b>16%</b>	<b>9%</b>	<b>31%</b>
Other	11%	12%	14%	10%	12%	10%
Sample size (n)	381	68	132	316	248	201

**TABLE 3 – Perceptions of Use**

	Disagree or Strongly Disagree	Neither agree or disagree	Agree or Strongly Agree	Don't know	n
<b>My top speed is higher than when I rode a standard bike</b>					
All respondents	23%	9%	68%	0%	447
Male	23%	9%	68%	1%	372
Female	23%	9%	68%	0%	69
Under 55	25%	9%	65%	0%	244
55 and Older	20%	8%	71%	1%	197
Respondents with physical limitation	16%	11%	74%	0%	129
Respondents without physical limitation	26%	8%	65%	1%	311
<b>My average speed is higher than when I rode a standard bike</b>					
All respondents	10%	5%	84%	1%	447
Male	10%	4%	86%	1%	372
Female	12%	10%	77%	1%	69
Under 55	9%	5%	86%	0%	244
55 and Older	12%	5%	82%	1%	197
Respondents with physical limitation	8%	7%	85%	0%	128
Respondents without physical limitation	11%	4%	84%	1%	312
<b>I don't need to shower at the end of the trip</b>					
All respondents	10%	14%	74%	1%	450
Male	11%	14%	74%	1%	376
Female	6%	18%	77%	0%	68
Under 55	<b>8%</b>	<b>12%</b>	<b>80%</b>	<b>0%</b>	243
55 and Older	<b>13%</b>	<b>18%</b>	<b>68%</b>	<b>2%</b>	201
Respondents with physical limitation	11%	19%	69%	2%	131
Respondents without physical limitation	10%	12%	77%	1%	312
<b>To ride the same trip by standard bike I would need a shower</b>					
All respondents	12%	20%	67%	2%	436
Male	11%	19%	69%	2%	363
Female	19%	24%	55%	2%	67
Under 55	<b>17%</b>	<b>15%</b>	<b>67%</b>	<b>1%</b>	242
55 and Older	<b>6%</b>	<b>25%</b>	<b>66%</b>	<b>3%</b>	188
Respondents with physical limitation	8%	20%	70%	2%	124
Respondents without physical limitation	13%	19%	65%	2%	305
<b>I feel safer on the e-bike than on a standard bike</b>					
All respondents	15%	23%	60%	2%	447
Male	<b>16%</b>	<b>22%</b>	<b>61%</b>	<b>1%</b>	374
Female	<b>12%</b>	<b>28%</b>	<b>54%</b>	<b>6%</b>	67
Under 55	12%	25%	63%	1%	244
55 and Older	20%	21%	56%	2%	197
Respondents with physical limitation	15%	21%	61%	4%	130
Respondents without physical limitation	16%	24%	60%	1%	310
